Hydrogeologic characterization and groundwater flow model analyses in Modesto, California CRC Press

This CD contains a 125-page comprehensive study of the hydrogeology of Cedar Valley, Utah County, located in north-central Utah. The report includes 72 figures; two plates, one of which is a potentiometric map of the basin-fill, bedrock, and several perched aquifers; and seven appendices of data. Field investigations included groundwater

chemistry sampling, regular water-level monitoring, and multiple-well aquifer testing. The field data were incorporated into a 3D digital groundwater flow model using MODFLOW2000. Seventy percent of the recharge to the Cedar Valley aquifer system is from precipitation in the Oquirrh Mountains. Groundwater generally flows from west to east and exits the aquifer system mostly as interbasin flow through bedrock to the northeast and southeast. The groundwater model showed a 39-year (1969-2007) average recharge to the Cedar Valley groundwater system of 25,600 acre-feet per year and discharge of 25,200 acre-feet per year. A significant volume of precipitation recharge (perhaps 4300 acre-feet per year) does not interact with the basin-fill aquifer but travels within bedrock to discharge to adjacent valleys or as bedrock well discharge. 125 pages + 2 plates

Hydrogeology and a Mathematical Model of Ground-water Flow in the Pullman-Moscow Region, Washington and Idaho Academic Press

The Lost Creek Designated Ground Water Basin (Lost Creek basin) is an important alluvial aquifer for irrigation, public supply, and domestic water uses in northeastern Colorado. Urban growth in the adjacent Front Range urban corridor has increased demand for groundwater in the basin, and potential exportation of groundwater from the basin has raised concerns about the long-term sustainability and management of the basin's groundwater resources. Beginning in 2005, the U.S. Geological Survey, in cooperation with the Lost Creek Ground Water Management District and the Colorado Water Conservation Board, collected hydrologic data and constructed a numerical groundwater flow model of the Lost Creek basin. The steady-state model builds upon the work of previous investigators to provide an updated tool for simulating the potential effects of various hydrologic stresses on groundwater flow and evaluating possible aquifer-management strategies.

Hydrogeology and Computer Modeling of

Groundwater Flow in a Glacial Aquifer, Dundee, New York John Wiley & Sons
Elevated groundwater nitrate (NO₃ -) concentrations in the Southern Willamette Valley (SWV) caused the Oregon Department of Environmental Quality (ODEQ) to declare a Groundwater Management Area (GWMA) in Spring, 2004. To better understand direction of groundwater flow, groundwater age, and nitrate transport pathways of the SWV we developed a steady-state numerical groundwater flow model using MODFLOW with MODPATH. Model development was supplemented by field investigations of local outcrops, pump and slug tests, and laboratory analyses to determine groundwater age and groundwater chemistry. Field work included the construction/collection of cross-sections and stratigraphic columns; 12 slug tests and 3 pump tests to determine hydraulic conductivity and storativity; 10 groundwater ages using CFC-11, CFC-12, and CFC-113; 3 wells instrumented to collect long-term continuous water level measurements; 42 wells selected for quarterly manual water level measurements; and 14 groundwater samples to determine pH, dissolved oxygen, specific electrical conductance, chloride, sulfate, and nitrate concentrations. Slug tests determined horizontal hydraulic conductivities (K_x) from 4.19 x 10⁻⁸ m/s to 4.62 x 10⁻⁴ m/s. Pump tests determined K_x-values from 3.59 x 10⁻⁴ m/s to 7.22 x 10⁻³ m/s, vertical hydraulic conductivities (K_v) from 3.48 x 10⁻⁶ m/s to 3.84 x 10⁻⁶ m/s, and storage coefficients from 0.05 to 0.15. Groundwater age ranged from 13 years to >50 years, with the greatest ages resulting from wells that penetrated the semi-confining Willamette Silt. Groundwater ages were compared to model particle travel times using MODPATH and used as calibration targets. Groundwater ages along with nitrate, chloride, sulfate, and dissolved oxygen concentrations were used to reconstruct past contaminant loading and observe

data trends. Spatial distributions of hydraulic conductivity were estimated using wells with specific capacity data and an empirical relationship ($T = 158.48sc$, where T = transmissivity (ft²/d) and sc = (gal/min/ft); $R^2 = 0.61$) between wells in the study area that contained both specific capacity and aquifer test data. The calibrated groundwater flow model is intended to help make management decisions, establish monitoring programs, and to be used as an outreach education tool. Model simulations were run in key areas to demonstrate model capabilities and create visual aids for outreach education. This study suggests it may take 10's of years to see measurable declines of groundwater nitrate in some locations. It is our hope that educating stakeholders about local groundwater flow along with stressing the use of Best Management Practices (BMPs) will result in better decision making and lead to a reduction of groundwater nitrate concentration in the SWV.

Hydrogeology and Steady-State Numerical Simulation of Groundwater Flow in the Lost Creek Designated Ground Water Basin, Weld, Adams, and Arapahoe Counties, Colorado CRC Press

Groundwater is a vital source of water throughout the world. As the number of groundwater investigations increase, it is important to understand how to develop comprehensive quantified conceptual models and appreciate the basis of analytical solutions or numerical methods of modelling groundwater flow. *Groundwater Hydrology: Conceptual and Computational Models* describes advances in both conceptual and numerical modelling. It gives insights into the interpretation of field information, the development of conceptual models, the use of computational models based on analytical and numerical techniques, the assessment of the adequacy of models, and the use of computational models for predictive purposes. It focuses on the study of groundwater flow problems and a thorough analysis of real practical field case studies. It is divided into three parts: * Part I deals with the basic principles, including a summary of mathematical descriptions of groundwater flow, recharge estimation using soil moisture balance

Regional Groundwater Flow Model of the Pinal Active Management Area CRC Press

A groundwater flow model encompassing approximately 4 mi² within C Reactor area has been developed. The objectives and goals of the C Reactor Area groundwater model are to: Provide a common hydrogeologic and groundwater flow modeling framework for C Area that can be easily updated as additional field data is collected from waste site investigations. Provide a baseline groundwater flow model for use in subsequent flow and transport simulations for remedial/feasibility studies for C Area waste sites. Provide baseline transport simulations for CBRP and CRSB that reconstruct historical contaminant distributions and simulate future plume migration from each waste unit. Provide a working groundwater flow model for particle tracking and analysis to guide subsequent field characterization activities. The model incorporates historical and current field characterization data up through spring 1999. The model simulates groundwater flow within the area bounded to the west and north by Fourmile Branch, to the south by Caster Creek, and to the east by a line between Fourmile Branch and the headwaters of Caster Creek. Vertically the model extends from ground surface to the top of the Gordon aquifer. The chosen areal grid is 14,600 by 13,200 feet with a resolution of 200 feet. The model accurately reproduces

groundwater flow directions from the CBRP and CRSB, and matches targets for hydraulic head, recharge and baseflow within calibration goals. The hydrogeologic model reflects aquifer heterogeneity as derived from CPT lithologic data.

This thesis presents a hydrogeologic study of the Parrett Mountain Region, located approximately 20 miles south of Portland, Oregon. The aim of the study was to investigate the impacts of Columbia River Basalt on the regional groundwater system, to expand our understanding of flow through fractured basalt, to improve management practices in the area, and to provide local detail for a regional groundwater model being developed by the USGS. An equivalent porous medium model with steady state heads was developed of the area using MODFLOW, a finite difference method for modeling groundwater flow. The data used to develop the model included (1) geologic stratigraphy of the area; (2) time averaged 1995-1996 water level data; and (3) local hydraulic properties measured by aquifer pump tests. Based on the hydrogeologic study we determined that using a continuum approach was the most appropriate method for modeling the flow system. We also found that during model calibration no faults were necessary to reach calibration goals, suggesting that faults do not play a significant role in regional groundwater flow at steady state. Finally, based on available data, we were unable to determine the role of basalt flow tops on groundwater flow. By using the calibrated flow model the impact of projected population increases were investigated to aid in groundwater management practices. Based on assumptions of uniform population increases and a uniform pumping distribution, it was found that an increase of approximately 8,000 people would result in drawdown estimates of less than 2 meters throughout the model.

Hydrogeology and Groundwater Flow Modeling for the Williams Creek Watershed, Postville, Iowa Springer

This text combines the science and engineering of hydrogeology in an accessible, innovative style. As well as providing physical descriptions and characterisations of hydrogeological processes, it also sets out the corresponding mathematical equations for groundwater flow and solute/heat transport calculations. And, within this, the methodological and conceptual aspects for flow and contaminant transport modelling are discussed in detail. This comprehensive analysis forms the ideal

textbook for graduate and undergraduate students interested in groundwater resources and engineering, and indeed its analyses can apply to researchers and professionals involved in the area.
